

Package ‘fluxweb’

December 5, 2017

Type Package

Title Estimate energy fluxes in food webs

Version 0.1.0

Author Benoit Gauzens

Maintainer Benoit Gauzens <benoit.gauzens@gmail.com>

Description

fluxweb is a package to compute energy fluxes from resources to their consumers and can be applied to systems ranging from simple two-species interactions to highly complex food webs. It implements the approach described in Gauzens et al. (Hopefully published ahead of time) to calculate energy fluxes, which are also used to calculate equilibrium stability.

fluxweb-package	<i>The fluxweb package</i>
-----------------	----------------------------

Description

the new fancy package fluxweb that fluxes webs

Author(s)

Benoit Gauzens

fluxing	<i>generate fluxes</i>
---------	------------------------

Description

Creates a valuated graph adjacency matrix from its binary version.

Usage

```
fluxing(mat, biomasses = NULL, losses, efficiencies, bioms.prefs = TRUE,
        bioms.losses = TRUE, ef.level = "prey")
```

Arguments

mat	Network adjacency matrix describing interactions among species. Interactions can be either binary or weighted.
biomasses	Vector of species biomasses.
losses	A vector or an array of species energy losses (excluding consumption).
efficiencies	A vector or an array of conversion efficiencies of species in the adjacency matrix. These values describe the proportion of consumed energy that is converted to biomass of the consumer.
bioms.prefs	Logical - if TRUE, consumer preferences are scaled according to species biomasses.
bioms.losses	Logical - if TRUE, losses are scaled with species biomasses.
ef.level	Set to "prey" if efficiencies are defined by prey, "pred" if they are a property of the predator.

Details

This function computes fluxes in food webs based on an equilibrium hypothesis: for each species, sum of ingoing fluxes (gains from predation) balances the sum of outgoing fluxes. Outgoing fluxes are defined by consumption and the losses argument. Usually losses relate to species metabolic rates and/or natural death rates. For each species i , sum of ingoing fluxes F_i is computed as:

$$F_i = \frac{1}{e_i} (L_i + \sum_j W_{ij} F_j) \quad \text{if } \text{ef.level} == \text{"pred"}$$

$$F_i = \frac{L_i + \sum_j W_{ij} F_j}{\sum_j W_{ji} e_j} \quad \text{if } \text{ef.level} == \text{"pred"}$$

W set the matrix of preferences estimated from `mat`, according to `bioms.prefs`. L is the vector depicting sum of losses (scaled or not by biomasses, accordingly to `bioms.losses`) and e is the vector of species efficiencies.

- `mat`: Either a binary or a valuated matrix can be used. A non zero value for `mat[i,j]` means that species i is consumed by species j . Matrix entries would assess predator preferences on its prey, thus providing a binary matrix assumes no preferences.
- `losses`: Express species energetic losses not related to consumption. Usually metabolic or death rates. When an array is provided, losses associated to each species correspond to line sums.
- `efficiencies`: Determines how efficient species are to convert energy (see `ef.level` for more details). Providing an array will assume values depending on both prey and predator identity.
- `bioms.pref`: If TRUE, preferences W_{ij} of predator j on prey i are scaled accordingly to species biomass using the following formula:

$$W_{i,j} = \frac{\text{mat}[i,j] * \text{biomasses}[i]}{\sum_k \text{mat}[i,k] * \text{biomasses}[k]}$$

If FALSE, a normalisation on column values is performed.

- `bioms.losses`: Set to true, function will assume that losses are defined per biomass unit. Thus, total losses will be thereafter multiplied by biomass values for each species.
- `ef.level`: If "prey" (resp "pred"), the total amount of energy that can be metabolised from a trophic link will be determined by prey (resp pred) identity. "link.specific" assumes that efficiencies are defined for each trophic interaction and implies `efficiencies` parameter to be a matrix.

Value

Returns an adjacency matrix where entries are the computed energy fluxes between consumer species and their respective resources.

Author(s)

Benoit gauzens, <benoit.gauzens@gmail.com>

Examples

```
# first compute species per unit biomass metabolic rates using the metabolic theory:
losses = 0.1 * species.level$bodymasses^(-0.25)

# call of the function:
fluxing(species.level$mat, species.level$biomasses, losses, species.level$efficiencies, bioms.pref = TRUE, ef.le
```

groups.level	<i>Aggregated version of the Food web of a soil network ecosystem and species general information (species.level).</i>
--------------	--

Description

This dataset contains the matrix describing trophic interactions between trophic groups of a soil food-web (reference) as well as some ecological information on these groups: biomasses, body masses and and species composition.

Format

- a list of 5 elements:
- mat** the network adjacency matrix
- biomasses** groups total biomasses (g)
- bodymasses** group mean bodyamasses of species (g)
- efficiencies** group species mean assimilation efficiencies
- species.tgs** groups' species composition

make.stability	<i>making network stability</i>
----------------	---------------------------------

Description

Find the smallest multiplicator of a variable from losses insuring system stability

Usage

```
make.stability(val.mat, biomasses, losses, efficiencies, growth.rate,
  losses.scale = NULL, bioms.prefs = TRUE, bioms.losses = TRUE,
  ef.level = "prey", interval = c(1e-12, 1), ...)
```

Arguments

<code>val.mat</code>	A matrix describing fluxes between species (usually a result of fluxing function).
<code>biomasses</code>	A vector of species biomasses.
<code>losses</code>	A vector or an array of species energy losses (excluding predation).
<code>efficiencies</code>	A vector or an array of conversion efficiencies of species in the adjacency matrix. These values describe the proportion of consumed energy that is converted to biomass of the consumer.
<code>growth.rate</code>	A vector defining growth rate of basal species.
<code>losses.scale</code>	Defines a Column from losses multiplier value will apply to. (default NULL if multiplier independant of losses).
<code>bioms.prefs</code>	Logical, if TRUE (default) preferences are scaled accordingly to species biomasses.
<code>bioms.losses</code>	Logical, if TRUE (default) losses are scaled with biomass.
<code>ef.level</code>	Set to "prey" if efficiencies are defined by prey, "pred" if they are a property of the predator.
<code>interval</code>	Search interval for returned value.
<code>...</code>	Optional parameters for function uniroot

Details

The function assumes a monotonous increase of stability with multiplier value. Solution is estimated from the [uniroot](#) function, and stability using the [fluxing](#) function. Thus, accordingly to [uniroot](#) solving criteria, if stability values at the two extremum parts of the interval are of same sign, an error is raised.

Behavior of the multiplicative term depends on the type of losses:

- `losses.scale = NULL` and `is.vector(losses)`: multiplier will be applied to the losses vector.
- `losses.scale = NULL` and `is.matrix(losses)`: multiplier will be independant of any columns from losses.
- `losses.scale = FALSE` : multiplier always independant of losses.
- other values: should refer to an element of losses.

Value

A list from [uniroot](#) function.

See Also

[uniroot](#) for root estimate and [stability.value](#) for assessing system stability.

Examples

```
losses = 0.15 * groups.level$bodymasses^(-0.25)

# growth rates of basal species
growth.rates = rep(0.5, length(groups.level$biomasses[colSums(groups.level$mat) == 0]))

val.mat = fluxing(groups.level$mat, groups.level$biomasses, losses, groups.level$efficiencies, bioms.pref = TRUE)
make.stability(val.mat, groups.level$biomasses, losses, groups.level$efficiencies, growth.rates, ef.level = "pre")
```

sensitivity

sensitivity analysis

Description

Assesses how sensitive the results from argument function are to variability of input parameter through coefficient of variation.

Usage

```
sensitivity(fun.name, param.name, var, n, full.output = FALSE, ...)
```

Arguments

<code>fun.name</code>	Function to analyse.
<code>param.name</code>	Parameter from ... on which variation is applied.
<code>var</code>	Define the interval of uncertainty for the uniform law around x as $[x - x*var, x + x*var]$.
<code>n</code>	Number of replicates.
<code>full.output</code>	Logical, if TRUE all of n estimations of <code>fun.name</code> are returned. Only their mean otherwise.
<code>...</code>	Arguments to be passed to <code>fun.name</code> . Argument names must exactly match those of <code>fun.name</code> .

Details

At each replicate, a coefficient of variation is computed (relative to results obtained from `fun.name` without random variation). if `full.output` is FALSE (default) an object of the same type as the one produced by `fun.name` is returned, containing all of variation coefficients. If `full.output` is TRUE, a list of size n with of objects containing variation coefficient is returned.

Argument for ... should be passed with their names.

Value

Mean coefficient of variation in comparison to non randomised inputs among all the replicates.

Examples

```
# first compute species per unit biomass metabolic rates using the metabolic theory:
losses = 0.1 * species.level$bodymasses^(-0.25)

res = sensitivity(fluxing, "mat", 0.1, 5, full.output = TRUE, mat = species.level$mat, biomasses = species.level$biomasses)
res = sensitivity(fluxing, "efficiencies", 0.01, 50, mat = species.level$mat, biomasses = species.level$biomasses)

# growth rates of basal species
growth.rate = rep(0.5, length(species.level$biomasses[colSums(species.level$mat) == 0]))

val.mat = fluxing(species.level$mat, species.level$biomasses, losses, species.level$efficiencies)
#sensitivity(stability.value, "efficiencies", 0.01, 50, val.mat = val.mat, biomasses = species.level$biomasses,

cvs = c()
for (var in seq(0, 0.6, 0.05)){
  cvs = c(cvs, sensitivity(stability.value, "mat", var, 50, val.mat = val.mat, biomasses = species.level$biomasses))
}

plot(abs(cvs) ~ seq(0, 0.6, 0.05))
```

species.level	<i>Food web of a soil network ecosystem and species general information.</i>
---------------	--

Description

This dataset contains the matrix describing trophic interactions from a deutsch soil food-web (reference) as well as some ecological information on species: biomasses, body masses and and species names.

Format

a list of 5 elements:

mat the network adjacency matrix

biomasses species biomasses (g)

bodymasses species bodyamasses (g)

efficiencies species assimilation efficiencies

names species names

stability.value	<i>Estimates network stability</i>
-----------------	------------------------------------

Description

Computes resilience of the system through jacobian eigenvalues.

Usage

```
stability.value(val.mat, biomasses, losses, efficiencies, growth.rate,
  bioms.prefs = TRUE, bioms.losses = TRUE, ef.level = "prey",
  full.output = FALSE)
```

Arguments

val.mat	A matrix describing fluxes between species (usually a result of fluxing function).
biomasses	A vector of species biomasses.
losses	A vector or an array of species energy losses (excluding predation).
efficiencies	A vector or an array of conversion efficiencies of species in the adjacency matrix. These values describe the proportion of consumed energy that is converted to biomass of the consumer.
growth.rate	A vector defining growth rate of basal species.
bioms.prefs	Logical, if TRUE (default) preferences are scaled according to species biomasses.
bioms.losses	Logical, if TRUE (default) losses are scaled with biomass.
ef.level	Set to "prey" if efficiencies are defined by prey, "pred" if they are a property of the predator.
full.output	Logical, if TRUE function return supplementary informations.

Details

- **losses:** Express species energetic losses not related to consumption. Usually metabolic or death rates. When an array is provided, losses associated to each species correspond to line sums.
- **efficiencies:** Determines how efficient species are to convert energy (see `ef.level` for more details). Providing an array will assume values depending on both prey and predator identity.
- **growth.rate:** Growth rates of basal species defined in `growth.rate` should appear in the same order as in other arguments. For example the second value specified in `growth.rate` should set the growth rate of the second basal species found in `biomasses`.
- **bioms.pref:** If TRUE, preferences w_{ij} of predator j on prey i are scaled according to species biomass using the following formula:

$$w_{i,j} = \frac{mat[i,j] * biomasses[i]}{\sum_k mat[i,k] * biomasses[k]}$$

- `bioms.losses`: If TRUE, function will assume that losses are defined per biomass unit. Thus, total losses will be thereafter multiplied by biomass values for each species.
- `ef.level`: If "prey" (resp "pred"), the total amount of energy that can be metabolised from a trophic link will be determined by prey (resp pred) identity. "link.specific" assumes that efficiencies are defined for each trophic interaction and implies `efficiencies` parameter to be a matrix
- `full.output`: If TRUE, function result is a list of eigenvalues and eigenvectors of the jacobian matrix.#'

Value

Maximum eigenvalue of the jacobian matrix of a Lotka Voltera like system of equations. If `full.output`, Jacobian eigenvalues and eigenvectors are returned.
